

Debugging in RStudio*

Jackson Hoffart

* Adapted from Jennifer Bryan's ["What they Forgot to Teach You About R"](#)

```
mirror_mod = modifier_ob.  
set mirror object to mirror.  
mirror_mod.mirror_object =  
operation == "MIRROR_X":  
mirror_mod.use_x = True  
mirror_mod.use_y = False  
mirror_mod.use_z = False  
operation == "MIRROR_Y":  
mirror_mod.use_x = False  
mirror_mod.use_y = True  
mirror_mod.use_z = False  
operation == "MIRROR_Z":  
mirror_mod.use_x = False  
mirror_mod.use_y = False  
mirror_mod.use_z = True  
  
selection at the end -add  
mirror_ob.select= 1  
modifier_ob.select=1  
context.scene.objects.active  
("Selected" + str(modifier_ob.  
mirror_ob.select = 0  
= bpy.context.selected_object  
data.objects[one.name].select  
print("please select exactly  
  
-- OPERATOR CLASSES ----  
  
types.Operator):  
X mirror to the selected  
object.mirror_mirror_x"  
mirror X"  
  
context):  
context.active_object is not
```

Finding your bug is a process of confirming the many things that you believe are true – until you find one which is not true.

–Norm Matloff

debugging

- what do we do when code doesn't work as intended?
- some bugs can be easy to see/ fix
- some bugs appear only after many layers of calls
 - hard to find
 - hard to fix
- debugging is a **VAST** topic

debugging strategies in RStudio

- `traceback()` – to determine where a given error is occurring
- `print()`, `str()`, `cat()` or `message()` statement – output diagnostic information in code
- `browser()` – open an interactive debugger before an error
- `debug()` – automatically open a debugger at the start of a function call
- `trace()` – start a debugger at a location inside the function
 - (666th iteration of a loop for example)

debugging strategies in RStudio

- ➔ • `traceback()` – to determine where a given error is occurring
- `print()`, `str()`, `cat()` or `message()` statement – output diagnostic information in code
- ➔ • `browser()` – open an interactive debugger before an error
- ➔ • `debug()` – automatically open a debugger at the start of a function call
- `trace()` – start a debugger at a location inside the function

traceback()

- prints the call-stack of the last uncaught error
- useful when an error message isn't helpful

traceback()

```
> # a simple example of a multiple level function-call
> f <- function(x) x + 1
> g <- function(x) f(x)
>
> # bugger
> g("a")
Error in x + 1 : non-numeric argument to binary operator
>
> traceback()
2: f(x) at #1
1: g("a")
>
```

browser()

- added directly to the source code*
- stops execution from wherever it is called
- open's R's interactive (and powerful) debugger:
 - run any R command from "within the function"
 - access objects available in the function's **current** environment

*need to have access to the source code!

browser()

```
debugging.R x some_functions.R x
← → | ↗ | 📁 | ☑ Source on Save | 🔍
1 g <- function(x) {
2   # start debugging browser
3   browser()
4
5   return(f(x))
6 }
7
8 f <- function(x){
9   out <- x + 1
10
11   return(out)
12 }
```

```
Console | Terminal x | Jobs x
C:/Users/jacks/Desktop/debugging/ ↗
⏪ ≡ Next | { } | ⏩ = | ⏴ Continue | ■ Stop
> source("some_functions.R")
>
> g("a")
Called from: g("a")
Browse[1]> |
```

browser() syntax

- `ls()` - to determine objects in **current** environment
- `str()`, `print()`, `etc.` - inspect objects in the **current** environment
- `n` - to evaluate the next statement
- `s` - to evaluate the next statement, but step into the function calls
- `where` - to print a stack trace
- `c` - to leave the debugger and continue execution
- `Q` - to exit the debugger and return to the R prompt

debug() & debugonce()

- similar to `browser()`
- `debug()` et al. open a debugger instance
- instead of embedding in function, you set a “debug flag”
- useful if you don’t have the source code
- `debug()` sets this flag permanently (call `undebug()` to turn off)
- `debugonce()` sets flag only for the next time it is called

debug() & debugonce()

- similar to `browser()`
- `debug()` et al. open a debugger instance
- instead of embedding in function, you set a “debug flag”
- useful if you don’t have the source code
- `debug()` sets this flag permanently (call `undebug()` to turn off)
- `debugonce()` sets flag only for the next time it is called
